If you buy a wireless transceiver for a specific use, how can you secure it and make sure you don't make any compromises (at the chip level)? A: Well, I'd start by encrypting it using an appropriate algorithm. A good reference for encryption protocols is the Handbook of Applied Cryptography, by Bruce Schneier. (A typical protocol in use is AES with 128-bit keys, and this book has all the details.) It wouldn't be difficult to design your own encryption algorithm if you were very determined, but that's a project you would want to do if you want to preserve the benefits of symmetric encryption. (You'd want to have the key length and key management down to get the best security.) But if your "chip" is a general purpose PC, there are plenty of commercial products that can be used. The most popular is probably TrueCrypt, which lets you create a volume which can be mounted using your favorite file system (on top of the Windows file system, if you want to be obscure). (Of course if you don't want to create your own encryption system, you could go for a commercial encryption product.) If you're looking to do some actual cryptanalysis, you might be better off using a tool such as libsnark to do that kind of thing, and have the cryptanalysis return a certificate that can be checked by your own tools. A: Chip level security is a very tall order. Take a look at this post. in the form of a microporous membrane is liable to be attached to a cell due to the adsorption of a salt solution to an anion exchange resin. Further, since only the anion exchange resin is in the hydrophilic state, the hydrophilic state of the resin 2d92ce491b
