Scientists have discovered that a common agricultural chemical can cross the placental barrier in human fetuses. Fetuses are usually protected by amniotic fluid and an ultra-thin membrane that is impermeable to many chemicals. But a new study reveals that the placental barrier, which is found only in humans, is permeable to two common pesticides — triadimefon and propiconazole. “Honey bees, big fish and women are all ‘impermeable’ to insecticide. But honey bees are extremely permeable to propiconazole,” said the study’s senior author Rolf Halden, a professor of developmental physiology at the University of Cambridge. “This has important implications for how the environment can affect the developing human.” This may be the first time that a pesticide has been discovered to cross the placental barrier. The study was published Monday in the journal PLOS ONE. Halden and colleagues from Cambridge, Harvard University and the University of Ghent in Belgium dosed pregnant mice with propiconazole and triadimefon. They found that both of these chemicals were passed from the mother to the offspring. Pregnant mice generally pass chemicals to their offspring through the placenta. However, the chemicals were not passed through to the fetuses, except in one instance where the mother was allowed to give birth. This was the only time the newborn baby was exposed to triadimefon. While this study looked at only two insecticides, the researchers suspect that the placental barrier is permeable to many other chemicals. “They are permeable to many pesticides,” Halden said. Insecticides are often connected to the development of autism in children. This has been related to the pesticides’ ability to affect the developing brain. The new study could explain, in part, why some children are exposed to chemicals at certain times in their development and then become more susceptible to autism when they reach young adulthood. The study’s authors hope to learn more about the placental barrier to develop tests that can detect whether the barrier has been breached. However, they note that it is difficult to develop tests that can identify whether the chemicals were internalized into the fetuses or transposed across the placenta. That makes testing more challenging. Synthesis, properties and cytotoxicity of diphenylidim
